

2-1

Observations

2-2

Positions on Earth

λ : geographic longitude (deg),

φ : geographic latitude (deg)

$\lambda = 0^\circ$ defined by position of a meridian circle in Greenwich (London)

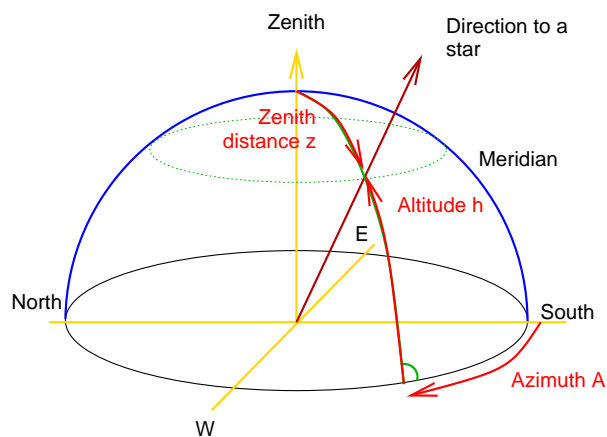

Coordinates

1

2-3

Horizon System

after Giese

Position on sky:

- Define position by giving direction to star.
- Azimuth A : angle in horizontal S-W-N-E
- Altitude h : angle from horizon towards zenith
- Zenith distance z : $z = 90^\circ - h$

http://joeorman.shutterace.com/Trails/Trails_021227_5.html

Earth rotates: A , h do not define position of stars at any time

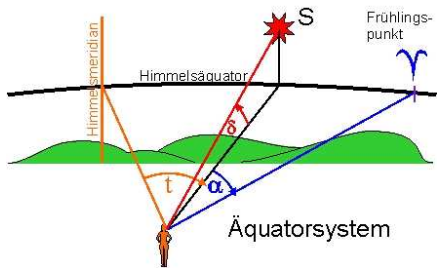

Coordinates

6

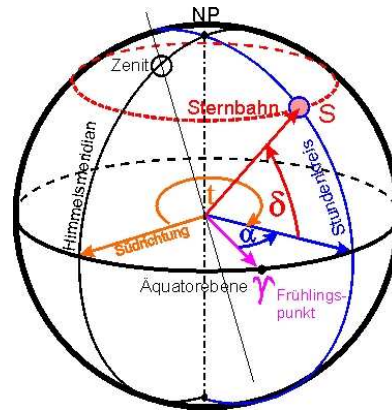

Equatorial System, fixed

2-5

t = hour angle (h,m,s), changes constantly with time
 δ = declination (deg), constant with time

Coordinates

8

Equatorial System, co-moving

2-7

Note: Siderial time \neq common time

Common time: 24 h between culminations of the Sun (i.e., passes of Sun through meridian).

BUT

Sun moves on sky towards east

\Rightarrow one "solar day" takes slightly longer than one rotation of the Earth

Angular speed of Sun: 360° degrees in 365.25 days, i.e., $0.9856^\circ \text{ d}^{-1}$.

\Rightarrow During 365.25 days the Earth rotates 366.25 times

\Rightarrow Earth's rotation takes $24 \text{ h} \times 365.25 / 366.25 = 23 \text{ h } 56 \text{ minutes}$.

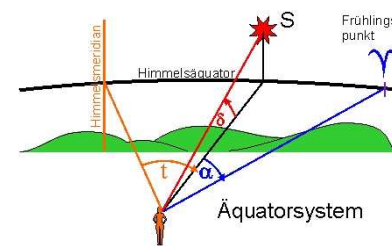

Coordinates

10

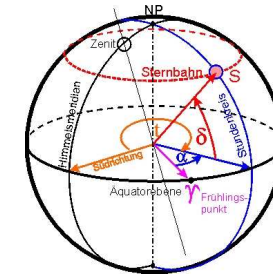

Equatorial System, co-moving

2-6

correct for earth rotation
 \Rightarrow use vernal equinox as a co-rotating zero point on the sky
 α = Right ascension (h,m,s) measured from vernal equinox
 δ = declination

Θ siderial time = hour angle of the vernal equinox
 transformation from fixed to co-moving equatorial system:

$$\Theta = t + \alpha$$

Coordinates

9

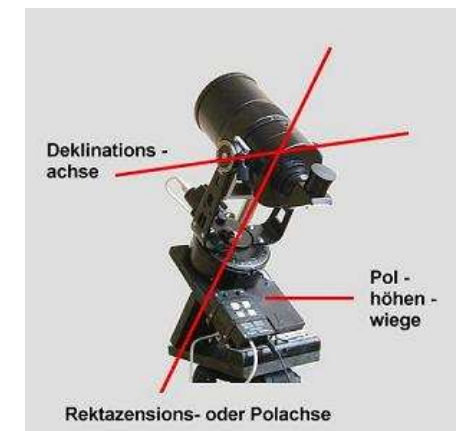

Telescope Mountings

2-8

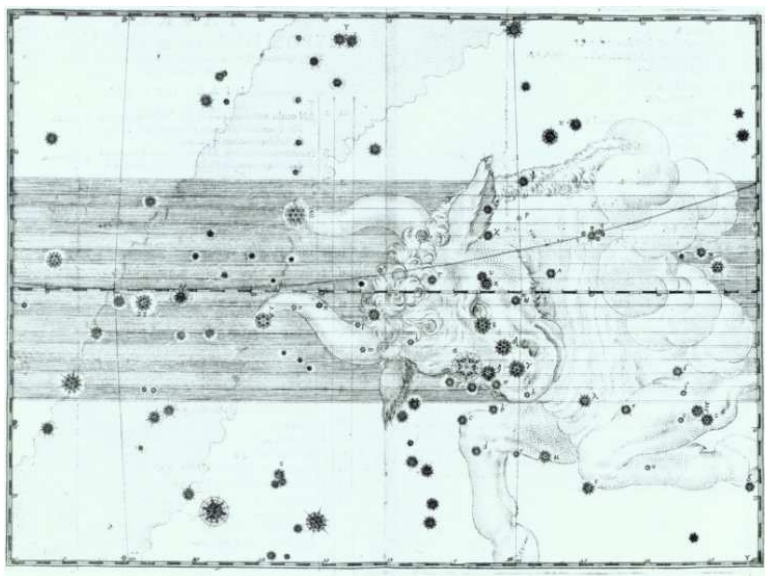

azimuthal mounting: horizontal axis and vertical axis

equatorial mounting: declination axis and polar axis

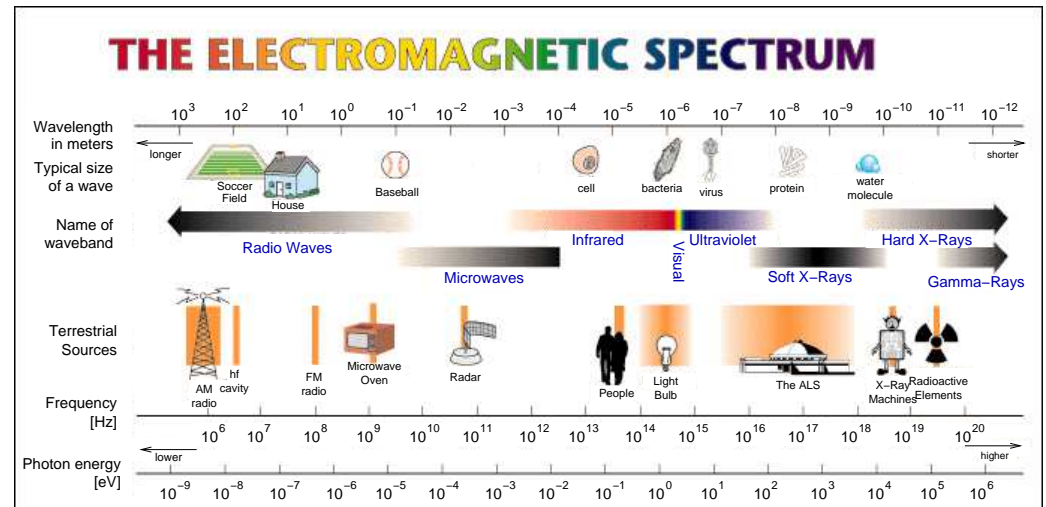

Coordinates

11

Bayer's Uranometria (1603; University of Illinois collections)

Because of precession and nutation: need to state epoch of coordinate!
 Aldebaran = α Tau: $\alpha_{J2000.0} = 04^h35^m55.2387^s$, $\delta_{J2000.0} = +16^\circ30'33.485''$
 corresponding to $\alpha_{B1950.0} = 04^h33^m02.9^s$, $\delta_{B1950.0} = +16^\circ24'37.6''$

Electromagnetic Spectrum

2-11

As we all know, light can be characterized by

Wavelength: λ , measured in m, mm, cm, nm, Å.

Frequency: ν , measured in Hz, MHz.

Energy: E , measured in J, erg, Rydbergs, eV, keV, MeV, GeV.

Temperature: T , measured in K.

These quantities are related:

$$\lambda \nu = c \quad E = h \nu \quad T = E/k \quad (2.1)$$

where

$$c = 299792458 \text{ m s}^{-1} \quad (2.2)$$

$$h = 6.6260693(11) \times 10^{-34} \text{ J s} \quad (2.3)$$

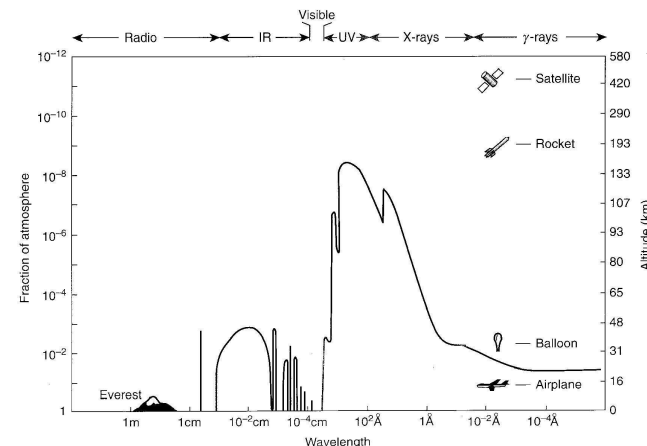

$$k = 1.3806505(24) \times 10^{-23} \text{ J K}^{-1} \quad (2.4)$$

Constants are 2002 CODATA values, <http://physics.nist.gov/cuu/Constants/index.html> uncertainty is 1 σ in units of last digit shown.

Earth's Atmosphere

2-12

Charles & Seward, Fig. 1.12

⇒ For time reasons only optical telescopes will be discussed.

Earth's atmosphere is opaque for all types of EM radiation except for optical light and radio.

⇒ Astronomy is today multi-wavelength astronomy, although optical studies are still very important

2-13

Introduction

Scientific purposes of a telescope:

1. Collect light, lots of light, to show faint objects ("Light bucket")
2. Resolve small features

Instrumentation used...

1. to make images
⇒ Imaging (with Charge Coupled Devices [CCDs], formerly also with film)
2. to measure spectra
⇒ Spectrographs
3. to measure stellar brightness
⇒ Photometers (often CCDs, but there are also dedicated photometers for msec-resolution photometry)

Optical Telescopes

4

2-14

Types of Telescopes

To collect light, we have two possibilities:

1. Lenses: Refractors

Disadvantage: lens cannot be supported from the back

⇒ limits max. diameter to $\lesssim 1$ m

largest refractor at Yerkes Observatory (University of Chicago): $d = 1.02$ m

⇒ not of interest for science

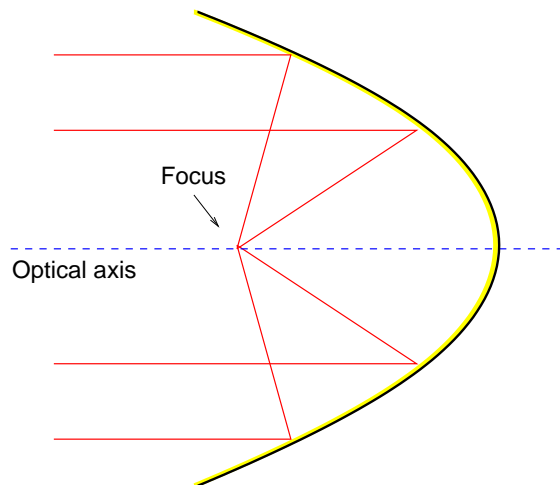

2. Mirrors: Reflectors

Mirrors can be supported, instrument of choice for today, with diameters up to 11 m

2-15

Types of Telescopes

To form image: focus light with a parabolic mirror

Spherical mirrors show spherical aberration ⇒ *not* suited for astronomical telescopes (at least not without correction).

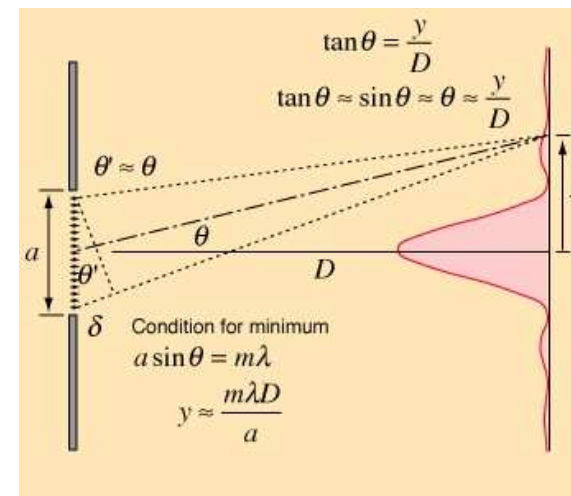

Optical Telescopes

6

2-16

Resolution

GSU

Wave nature of light results in interference pattern caused by diffraction on optical elements in telescope (mainly aperture).

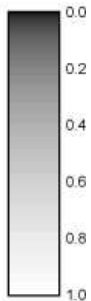

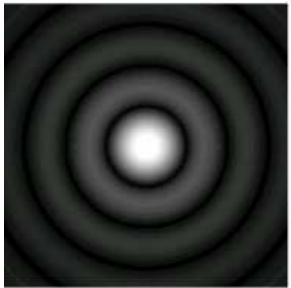

Optical Telescopes

7

2-17

Resolution

Diffraction pattern on telescope aperture: Airy pattern
For a circular aperture with radius r :

$$I(\theta) \propto \pi^2 r^4 \left[\sum_{n=0}^{\infty} (-1)^n \frac{1}{n+1} \left(\frac{m^n}{n!} \right)^2 \right]^2 \quad (2.5)$$

$$\propto \frac{\pi^2 r^4}{m^2} (J_1(2m))^2$$

where $m = \pi(r/\lambda) \sin \theta$ and where $J_1(x)$ is the Bessel function of the first kind of order unity.

$I(\theta)$ has minima for $m = 1.916, 3.508, 5.087, \dots$, or

$$\sin \theta = \frac{1.916\lambda}{\pi r}, \frac{3.508\lambda}{\pi r}, \frac{5.087\lambda}{\pi r}, \dots \quad (2.6)$$

or for θ small ($\sin \theta \sim \theta$) minima are found at:

$$\theta = \frac{1.220\lambda}{d}, \dots \quad (2.7)$$

where d : diameter.

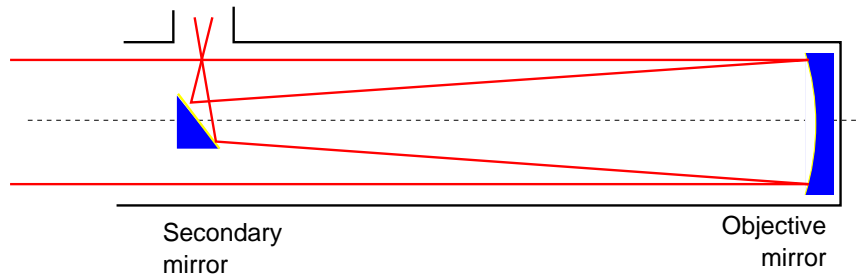

Optical Telescopes

8

2-19

Newtonian Telescope

Newtonian telescope: reflector with parabolic mirror.

Common in cheaper telescopes.

Disadvantage: large size (\sim focal length)

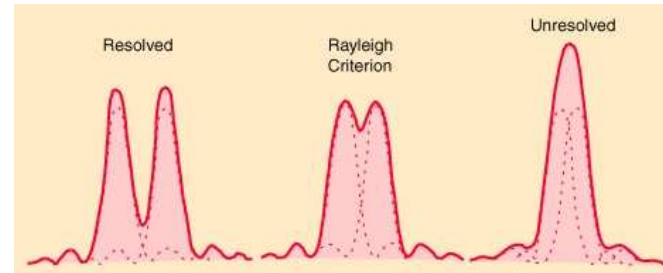

Optical Telescopes

10

2-18

Resolution

Resolution of telescope:
ability to separate two
(point-like) light sources

Rayleigh criterion for resolution: maximum of diffraction pattern of one source must fall into minimum of diffraction pattern of other source.

Therefore the diffraction limited resolution is

$$\alpha = \frac{1.220\lambda}{d} = \frac{12''}{D/1 \text{ cm}} \quad \text{for optical light} \quad (2.8)$$

Note: Rayleigh criterion is a criterion, *not* a law. Detailed object separability depends on ratio of intensities of two objects, in practice resolutions up to $3\times$ smaller are achievable.

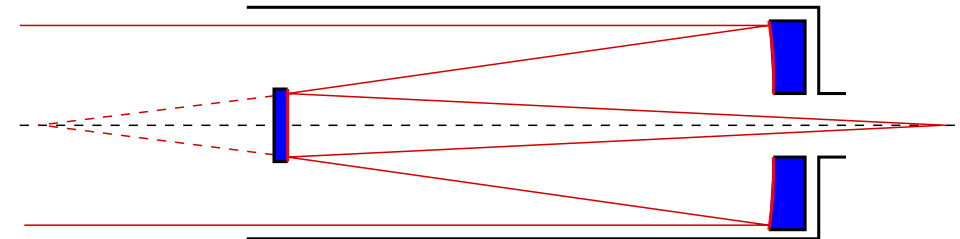

Optical Telescopes

9

2-20

Cassegrain Telescope

Cassegrain telescope, after Wikipedia

Cassegrain telescope: reflector with “folded optical path”

(M1: paraboloid, M2: hyperboloid)

\Rightarrow Much shorter than Newtonian

\Rightarrow Telescope of choice for modern instruments

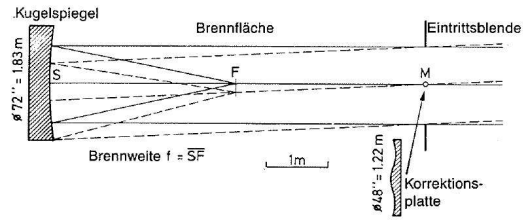

Optical Telescopes

11

Schmidt Telescope

2m Schmidt telescope at the Landesternwarte Thüringen in Tautenburg near Jena:
largest Schmidt telescope in the world.

Uses spherical mirror for larger field view, correction plate used to correct for spherical aberration.

Many amateur telescopes are combination of Schmidt telescope and Cassegrain telescope
⇒ Schmidt-Cassegrain telescopes.

European Southern Observatory

Mirror cell supporting the mirror, actuators keep mirror in shape ("active optics", correcting all possible deformations of the mirror).

Building the VLT

Nasmyth Focus:

light reflected through axis

- ideal for modern azimuthal mountings
- e.g., European Southern Observatory's Very Large Telescope
- two stationary platforms
- can host large instruments
- very stable

Adaptive Optics

From Eq. 2.8, the resolution of a telescope of diameter d is

$$\alpha = \frac{1.220\lambda}{d} = \frac{12''}{D/1 \text{ cm}} \quad (2.8)$$

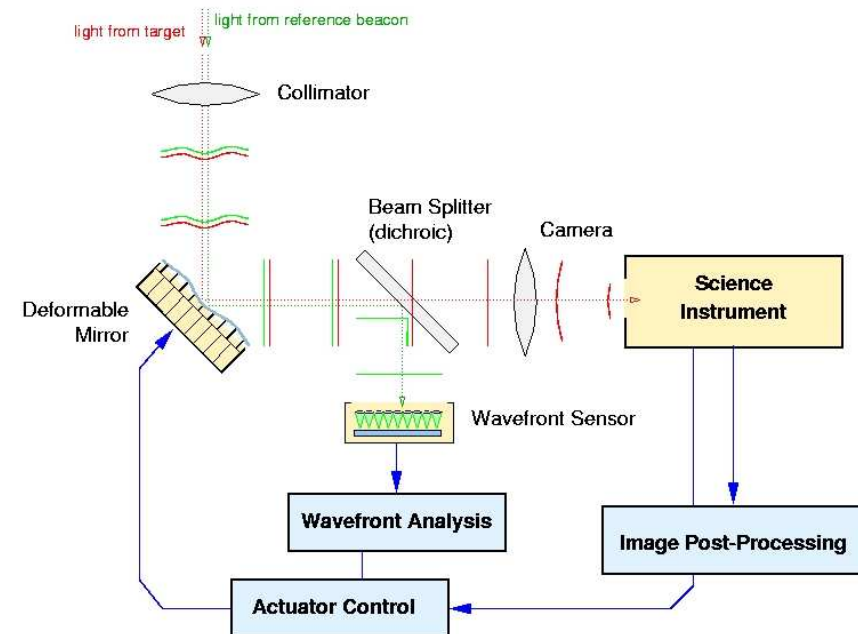

Problem: astronomical seeing

⇒ turbulence in atmosphere smears pictures of stars to disks with $\theta \gtrsim 0.3''$

⇒ Increasing telescope diameter to $\gtrsim 40$ cm does *not* result in increase in resolution!

Solution to seeing problem: adaptive optics

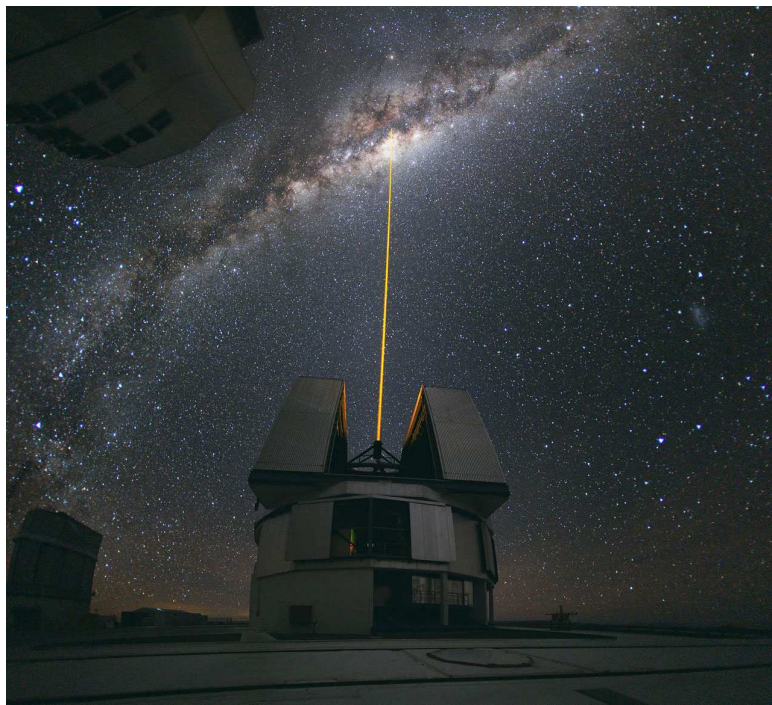

... which only works in the IR so far, need to go to space for optical and UV

Scheme of an adaptive optics system (Lick observatory)

CCDs

- linear detector
(photographic plate: nonlinear)
- high quantum efficiency: up to ~90%
(photographic plate: ~2%)

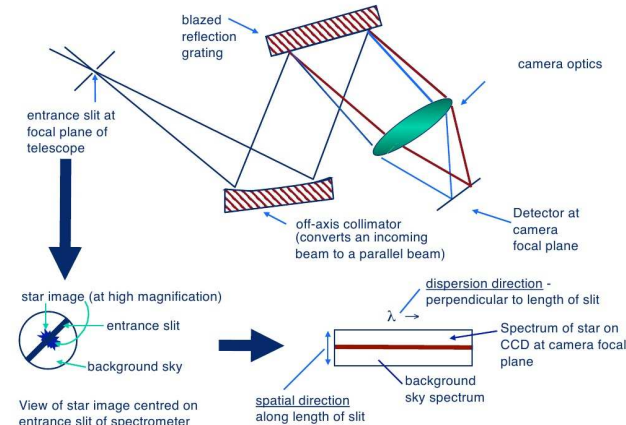

imaging of large fields of view: CCD arrays

- basics of operation:

Spectrographs

Grating spectrograph:schematic

Dispersion

- grating equation:

$$a(\sin \phi - \sin \phi_0) = n\lambda \quad (2.10)$$

a : grating constant; ϕ_0 : incident angle;
 ϕ : emergent angle; n : spectral order

- angular dispersion:

$$\frac{d\phi}{d\lambda} = \frac{n}{a \cos \phi} \quad (2.11)$$

- linear dispersion:

$$\frac{dx}{d\lambda} = f \cdot \frac{d\phi}{d\lambda} \quad (2.12)$$

f : focal length of camera

Spectral resolving power:

$$R = \frac{\lambda}{\Delta\lambda} = nN \quad (2.13)$$

N : number of grating rules

Instrumentation

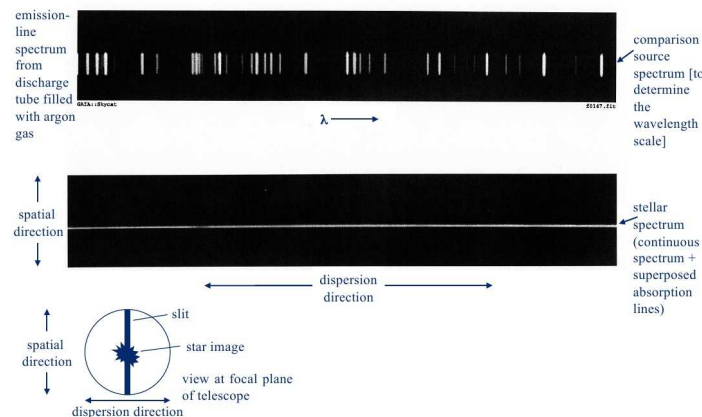

1

Instrumentation

2

Spectrographs

'Raw' spectra recorded by a CCD on a spectrometer

$R < 1000$: low; $R = 1000 \dots 10000$: intermediate; $R > 10000$: high resolution
